ANNOTATION

This article examines the role of the antioxidant defense system in the pathogenesis and progression of Nonalcoholic fatty liver disease (NAFLD) and its more severe form, Nonalcoholic steatohepatitis (NASH). It discusses how excessive lipid accumulation in hepatocytes leads to increased production of reactive oxygen species and oxidative stress. The paper outlines the key components of the antioxidant system, including enzymatic defenses such as superoxide dismutase, catalase, and glutathione peroxidase, as well as non-enzymatic antioxidants like glutathione and vitamins C and E. Particular attention is given to the imbalance between pro-oxidant and antioxidant mechanisms, which contributes to inflammation, cellular injury, and fibrosis. The article concludes that strengthening antioxidant defenses through lifestyle modification and targeted therapeutic strategies may help slow disease progression and improve liver health.

Key words: nonalcoholic fatty liver disease**,** nonalcoholic steatohepatitis, oxidative stress, antioxidant system, reactive oxygen species, glutathione, lipid peroxidation, liver fibrosis, metabolic syndrome, inflammation

ANNOTATSIYA

Ushbu maqolada alkogolsiz yog‘li jigar kasalligi (NAFLD) va uning og‘irroq shakli, alkogolsiz steatogepatit (NASH) patogenezi va rivojlanishida antioksidant himoya tizimining roli o‘rganiladi. Unda gepatotsitlarda lipidlarning haddan tashqari to‘planishi reaktiv kislorod turlarining ko‘payishi va oksidlovchi stressga olib kelishi muhokama qilinadi. Maqolada antioksidant tizimning asosiy komponentlari, jumladan, superoksid dismutaza, katalaza va glutation peroksidaza kabi fermentativ himoya, shuningdek, glutation va C va E vitaminlari kabi fermentativ bo‘lmagan antioksidantlar bayon etilgan. Yallig‘lanish, hujayra shikastlanishi va fibrozga olib keladigan pro-oksidant va antioksidant mexanizmlar o‘rtasidagi nomutanosiblikka alohida e'tibor qaratilgan. Maqolada turmush tarzini o‘zgartirish va maqsadli terapevtik strategiyalar orqali antioksidant himoyani kuchaytirish kasallikning rivojlanishini sekinlashtirish va jigar salomatligini yaxshilashga yordam berishi mumkinligi haqida xulosa qilingan.

Kalit so‘zlar: alkogolsiz yog‘li jigar kasalligi, alkogolsiz steatogepatit, oksidlovchi stress, antioksidant tizim, reaktiv kislorod turlari, glutation, lipid peroksidlanishi, jigar fibrozi, metabolik sindrom, yallig‘lanish

АННОТАЦИЯ

В данной статье рассматривается роль антиоксидантной защитной системы в патогенезе и прогрессировании неалкогольной жировой болезни печени (НАЖБП) и ее более тяжелой формы, неалкогольного стеатогепатита (НАСГ). Обсуждается, как чрезмерное накопление липидов в гепатитах приводит к увеличению образования активных форм кислорода и окислительному стрессу. В статье изложены ключевые компоненты антиоксидантной системы, включая ферментативные защитные механизмы, такие как супероксиддисмутаза, каталаза и глутатионпероксидаза, а также не ферментативные антиоксиданты, такие как глутатион и витамины С и Е. Особое внимание уделяется дисбалансу между прокиданными и антиоксидантными механизмами, который способствует воспалению, повреждению клеток и фиброзу. В заключение статьи делается вывод, что укрепление антиоксидантной защиты посредством изменения образа жизни и целенаправленных терапевтических стратегий может помочь замедлить прогрессирование заболевания и улучшить здоровье печени.

Ключевые слова: неалкогольная жировая болезнь печени, неалкогольный стеатогепатит, окислительный стресс, антиоксидантная система, активные формы кислорода, глутатион, перекисное окисление липидов, фиброз печени, метаболический синдром, воспаление

Introduction. Fatty liver disease, particularly Non-Alcoholic Fatty Liver Disease, has emerged as one of the most prevalent chronic liver disorders worldwide, affecting approximately one-quarter of the global population. It is closely associated with metabolic conditions such as Obesity, Type 2 Diabetes Mellitus, and dyslipidemia, making it a significant component of the modern non-communicable disease burden. The rapid increase in sedentary lifestyles, unhealthy dietary patterns, and urbanization has contributed to the growing incidence of this condition, particularly in developing and transitional countries.

At the cellular level, the pathogenesis of fatty liver disease is strongly linked to oxidative stress, a condition characterized by an imbalance between the production of reactive oxygen species (ROS) and the body's antioxidant defense mechanisms. The antioxidant system, which includes enzymatic components such as superoxide dismutase, catalase, and glutathione peroxidase, as well as non-enzymatic antioxidants like vitamins C and E, plays a critical role in protecting hepatocytes from oxidative damage. However, in fatty liver disease, excessive lipid accumulation in the liver promotes ROS generation, overwhelming these protective systems and leading to cellular injury, inflammation, and progression from simple steatosis to more severe forms such as steatohepatitis and fibrosis. From a public health perspective, antioxidant deficiency represents not only a biological mechanism but also a reflection of broader lifestyle and environmental factors, including poor nutrition, limited access to healthy foods, and inadequate health awareness. This highlights the importance of population-level interventions aimed at improving dietary habits, increasing physical activity, and reducing metabolic risk factors. Furthermore, early identification and management of oxidative stress-related liver damage are essential to prevent disease progression and reduce the long-term burden on healthcare systems.

Therefore, understanding the role of antioxidant deficiency in fatty liver disease provides a crucial link between molecular mechanisms and population health. It also offers valuable insights into prevention strategies and integrated management approaches that combine clinical care with public health initiatives.

Fatty liver disease, medically known as Nonalcoholic fatty liver disease (NAFLD), is one of the most common chronic liver disorders worldwide. It is characterized by excessive fat accumulation in liver cells in individuals who consume little or no alcohol. Closely associated with obesity, insulin resistance, type 2 diabetes, and metabolic syndrome, NAFLD can progress to more severe liver conditions, including inflammation, fibrosis, cirrhosis, and even liver cancer. A more aggressive form of this disease, Nonalcoholic steatohepatitis (NASH), involves liver inflammation and cellular injury in addition to fat accumulation.

A key factor in the progression from simple fat accumulation (steatosis) to more severe liver damage is oxidative stress. The antioxidant system plays a central protective role in defending liver cells against oxidative injury. Understanding how this system functions-and how its impairment contributes to disease development-is essential for grasping the pathogenesis of fatty liver disease.

Oxidative stress occurs when there is an imbalance between the production of reactive oxygen species (ROS) and the body's ability to neutralize them. In fatty liver disease, excessive fat accumulation in hepatocytes increases mitochondrial activity and fatty acid oxidation, leading to elevated ROS production. These highly reactive molecules can damage lipids, proteins, and DNA within liver cells. As fat builds up in the liver, lipid peroxidation becomes more prominent. This process generates toxic byproducts that trigger inflammation and activate hepatic stellate cells, contributing to fibrosis. Persistent oxidative stress is considered a major driving force in the transition from simple steatosis to NASH. The antioxidant system consists of both enzymatic and non-enzymatic defenses that work together to neutralize ROS and maintain cellular balance.

Key antioxidant enzymes include:

- **Superoxide dismutase (SOD):** Converts superoxide radicals into hydrogen peroxide.
- **Catalase:** Breaks down hydrogen peroxide into water and oxygen.
- **Glutathione peroxidase (GPx):** Reduces hydrogen peroxide and lipid peroxides using glutathione.

These enzymes form the first line of defense against oxidative damage in hepatocytes.

Non-enzymatic antioxidants include:

- **Glutathione (GSH):** A critical intracellular antioxidant that detoxifies reactive species.
- **Vitamins C and E:** Scavenge free radicals and protect cell membranes from lipid peroxidation.
- **Dietary polyphenols:** Found in fruits and vegetables, they provide additional antioxidant support.

In healthy liver tissue, these systems maintain redox balance and prevent oxidative injury. In NAFLD and NASH, the antioxidant system often becomes overwhelmed. Increased ROS production depletes glutathione levels and impairs enzyme function. Mitochondrial dysfunction further exacerbates oxidative stress, creating a vicious cycle of damage.

Reduced antioxidant capacity leads to:

- Enhanced lipid peroxidation
- Activation of inflammatory pathways
- Increased cytokine production
- Progression to fibrosis

Studies have shown that patients with fatty liver disease often exhibit decreased levels of glutathione and reduced activity of antioxidant enzymes, highlighting the importance of antioxidant defenses in disease prevention and progression. Because oxidative stress plays a central role in fatty liver disease, antioxidant-based therapies have gained attention. Lifestyle interventions such as weight loss, regular physical activity, and diets rich in natural antioxidants can improve liver function and reduce oxidative damage. Clinical trials have also explored antioxidant supplementation-such as vitamin E-in selected patients with NASH, with some promising results.

However, antioxidant therapy alone is not a complete solution. A comprehensive approach addressing insulin resistance, metabolic dysfunction, and inflammation is essential for effective management.

Conclusion. In conclusion, antioxidant deficiency plays a pivotal role in the development and progression of fatty liver disease, particularly Non-Alcoholic Fatty Liver Disease. The imbalance between excessive production of reactive oxygen species and weakened antioxidant defenses contributes to hepatocellular damage, inflammation, and the transition from simple steatosis to more severe liver conditions, including fibrosis and cirrhosis. This highlights oxidative stress as a key pathogenic mechanism linking metabolic disturbances to liver injury.

From a public health perspective, the growing prevalence of fatty liver disease-driven by conditions such as Obesity and Type 2 Diabetes Mellitus-underscores the urgent need for comprehensive prevention strategies. Addressing antioxidant deficiency requires not only clinical management but also population-based interventions focused on promoting balanced nutrition, increasing physical activity, and improving awareness of healthy lifestyles.

Effective management of fatty liver disease should therefore adopt an integrated approach that combines early detection, lifestyle modification, and, where appropriate, antioxidant-based therapeutic strategies. At the same time, health systems must prioritize policies that support disease prevention, strengthen primary healthcare services, and reduce exposure to modifiable risk factors.

Ultimately, bridging the gap between molecular understanding and public health action is essential to reduce the burden of fatty liver disease and improve long-term health outcomes.

The antioxidant system plays a crucial protective role in the development and progression of fatty liver disease. In conditions like Nonalcoholic fatty liver disease and its more severe form, Nonalcoholic steatohepatitis, excessive oxidative stress overwhelms the liver’s natural defense mechanisms. When antioxidant capacity declines, cellular injury, inflammation, and fibrosis follow. Understanding the interplay between oxidative stress and antioxidant defenses provides valuable insight into the pathogenesis of fatty liver disease and opens avenues for targeted therapeutic strategies. Strengthening the body’s antioxidant system-through lifestyle changes and potentially medical interventions-remains a promising approach in reducing disease progression and improving liver health.
