Abstract: The rapid development of artificial intelligence (AI) has significantly influenced the organization of distance and technology-mediated foreign language education. Artificial intelligence-based applications, including conversational agents, automated writing evaluation systems, machine translation, speech-recognition technologies, intelligent tutoring systems, and generative AI platforms, increasingly provide learners with opportunities for individualized practice, immediate feedback, adaptive content, and autonomous learning. This article examines the opportunities, challenges, and pedagogical implications of integrating AI into distance foreign language education. The study employs a qualitative literature-review methodology based on peer-reviewed academic publications and international educational reports. Particular attention is given to recent research on generative AI and large language models in foreign and second-language learning. Existing evidence indicates that AI-mediated interaction can support speaking practice, writing development, vocabulary acquisition, learner autonomy, and engagement. Research has also demonstrated that AI-based feedback can provide accessible and detailed linguistic assistance; however, its effectiveness should not be interpreted as evidence that AI can replace teachers. A study of AI-mediated speaking activities involving 65 EFL learners reported positive effects on speaking skills and willingness to communicate, while research on AI-generated writing feedback involving 48 learners found no statistically significant difference in learning outcomes compared with human-tutor feedback. These findings demonstrate that AI is most pedagogically valuable when integrated into teacher-guided learning rather than treated as an autonomous replacement for instruction. Major challenges include inaccurate or fabricated AI outputs, algorithmic bias, privacy and data-protection risks, academic integrity, unequal access to digital technologies, overdependence on automated assistance, and insufficient AI literacy among teachers and learners. The article concludes that effective implementation requires a human-centred pedagogical model in which AI functions as an instructional assistant while teachers retain responsibility for curriculum design, assessment, feedback, ethical supervision, and development of communicative and intercultural competence.

Keywords: artificial intelligence; distance education; foreign language education; English as a foreign language; generative AI; ChatGPT; conversational AI; intelligent tutoring systems; language learning; teacher mediation; digital literacy; learner autonomy

Introduction

The expansion of digital technologies has fundamentally changed the organization of foreign language education. Distance education, online learning platforms, video-conferencing systems, mobile applications, automated feedback systems, and computer-mediated communication have made language learning possible beyond the physical classroom. Artificial intelligence represents the next stage of this technological development because it can process linguistic data, recognize speech, generate texts, provide automated feedback, simulate conversations, and adapt learning activities to individual users.

The significance of this development is particularly clear in foreign language education, where learners require repeated exposure to the target language and opportunities for meaningful interaction. Traditional classroom environments are constrained by limited instructional time and teacher availability. AI-based systems can potentially expand the amount of language practice available to learners outside formal lessons. Earlier research on chatbots already identified their potential to provide learners with opportunities to communicate in the target language at flexible times and locations [1, pp. 8–14]. More recent developments in generative AI have substantially expanded these possibilities by enabling systems to produce context-sensitive responses, explanations, examples, dialogues, questions, and writing feedback.

The scale of digital education has also expanded globally. UNESCO reported that the proportion of the world's population using the internet increased from 16% in 2005 to 66% in 2022. Nevertheless, approximately 31% of students worldwide could not be reached by remote learning during school closures, demonstrating that technological innovation does not automatically eliminate educational inequality [2, pp. 28–44]. The same report emphasizes that educational technology should support, rather than replace, human interaction and that evidence concerning the educational effectiveness of technology remains uneven [2, pp. 66–84].

Artificial intelligence should therefore not be considered merely a technological innovation. Its integration changes the relationship between learners, teachers, educational content, assessment, and digital platforms. Hockly argues that contemporary AI in English language teaching offers significant opportunities but simultaneously raises concerns related to privacy, learner well-being, data collection, and digital literacy [3, pp. 445–451]. Consequently, the central question is not whether AI should be used in foreign language education, but under what pedagogical, ethical, and institutional conditions it can contribute to meaningful learning.

Recent systematic reviews demonstrate the rapid growth of academic interest in this field. A review of the first year of research following the public release of ChatGPT identified 523 initial records and selected 36 peer-reviewed studies for detailed analysis [4]. Another review examining ChatGPT specifically in second-language learning analyzed 44 studies and found that content generation, feedback, and teaching support were among its most frequent roles [5]. A bibliometric study of AI in language education identified 2,609 publications in the Web of Science database for the period 2018–2022, confirming that AI-supported language education had become a substantial research area [6, pp. 159–194].

The purpose of this article is to examine the opportunities and challenges associated with AI in distance foreign language education and to identify the pedagogical principles required for its responsible implementation.

Methodology

The article uses a qualitative literature-review methodology. The research was based on peer-reviewed journal articles, systematic reviews, international educational reports, and scholarly publications concerning artificial intelligence, computer-assisted language learning, distance education, generative AI, conversational AI, automated writing evaluation, and foreign-language pedagogy.

The literature selection prioritized sources that met three criteria. First, the source had to address AI, digital technologies, or technology-mediated foreign language learning. Second, priority was given to peer-reviewed publications and internationally recognized institutional reports. Third, empirical studies were used where numerical findings were required, while theoretical and review publications were used to analyze broader pedagogical and ethical implications.

Particular attention was given to recent research published after the emergence of ChatGPT in November 2022. This was necessary because generative AI differs considerably from earlier language-learning technologies. Earlier systems were frequently designed for specific functions such as grammar

correction, speech recognition, machine translation, or scripted conversation. Generative AI systems, by contrast, can perform several of these functions through natural-language interaction.

The analysis focused on five dimensions: opportunities for language learning, effects on language skills, learner autonomy and personalization, teacher roles, and ethical and technological challenges. Findings from empirical studies were compared with recommendations from UNESCO and broader research on educational technology.

The methodological approach recognizes an important limitation: the research field is developing rapidly, and many studies on generative AI are recent, exploratory, or based on relatively small samples. Therefore, the article does not claim that AI has a universally positive or negative effect. Instead, it synthesizes established findings and identifies areas where evidence remains insufficient.

Results

The literature demonstrates several major opportunities for using AI in distance foreign language education.

The first opportunity is individualized learning. Traditional distance education frequently provides identical materials to large groups of learners. AI can modify explanations, examples, vocabulary exercises, and practice tasks according to learners' responses. A learner who has difficulty with grammatical accuracy can request additional explanations and examples, while another learner can engage in more advanced communicative tasks. This capability is particularly relevant to distance education because learners often study independently without immediate access to a teacher.

The second opportunity concerns conversational practice. Foreign language learners need opportunities to use language actively rather than merely receive information. Early research by Fryer and Carpenter found that students used chatbots as language-learning tools and reported that many learners enjoyed interacting with them; some learners also felt more comfortable conversing with bots than with peers or teachers [1, pp. 8–14]. This finding is important for distance education because AI-based conversational agents can provide practice when human partners are unavailable.

Contemporary AI-mediated speaking systems offer more sophisticated interaction. Fathi, Rahimi and Derakhshan investigated AI-mediated speaking activities with 65 EFL learners, assigning 33 learners to an AI group and 32 to a face-to-face comparison group. The researchers reported that AI-mediated interactive speaking activities were more effective in improving speaking skills and willingness to communicate in their study [7]. The findings indicate that AI can create additional opportunities for speaking practice, although they should not be generalized to all learners or educational contexts.

The third opportunity is automated feedback. Writing is particularly suitable for AI-assisted learning because digital systems can identify grammatical, lexical, organizational, and stylistic problems. Godwin-Jones notes that contemporary AI writing tools have moved beyond conventional spelling and grammar correction toward more sophisticated forms of feedback and text generation [8, pp. 5–24]. This can be valuable in distance education because students may receive feedback outside normal teacher working hours.

However, the effectiveness of AI feedback requires careful interpretation. Escalante, Pack and Barrett conducted two longitudinal studies involving English as a new language learners. In the first study, 48 university students received either GPT-4-generated feedback or human-tutor feedback during a six-week intervention. The study found no statistically significant difference in learning outcomes between the groups. In the second study, involving a separate group of 43 learners, preferences were approximately evenly divided between AI-generated and human-generated feedback [9, pp. 1–20]. This finding is particularly important because it demonstrates that AI-generated feedback should not automatically be considered superior to teacher feedback.

The fourth opportunity is support for learner autonomy. Distance learners frequently need to manage their own time, identify learning needs, select resources, and monitor progress. AI can serve as

an accessible learning assistant that provides explanations, practice questions, vocabulary exercises, conversation simulations, and revision suggestions. Kohnke, Moorhouse and Zou argue that ChatGPT can be used for language teaching and learning but emphasize the importance of developing appropriate digital competencies among both teachers and learners [10, pp. 537–550].

The fifth opportunity concerns teachers' professional work. AI can assist teachers in generating preliminary lesson materials, creating exercises, adapting texts to different proficiency levels, producing discussion questions, and preparing formative assessment activities. Such applications may reduce repetitive administrative tasks and allow teachers to devote more time to interaction, feedback, and pedagogical decision-making.

The sixth opportunity is scalability. AI-based systems can potentially provide language practice to very large numbers of learners simultaneously. This is particularly relevant to distance education, where teacher availability may be limited. Nevertheless, scalability must not be confused with effectiveness. UNESCO emphasizes that educational technologies should be evaluated according to educational objectives and evidence rather than technological novelty [2, pp. 180–196].

The literature also identifies substantial challenges.

One of the most important challenges is reliability. Generative AI systems can produce grammatically fluent but factually incorrect information. UNESCO explicitly warns that generated text may appear human-like even though the system does not possess human understanding and that generated content can be incorrect or biased [11, pp. 14–17]. In foreign language education, such errors may include inaccurate definitions, inappropriate vocabulary, incorrect grammar explanations, fabricated references, or culturally inappropriate examples.

A second challenge is academic integrity. Generative AI can produce essays, summaries, translations, and answers to assignments. Sharples argues that transformer-based AI systems create new problems for conventional written assessment because they can generate substantial quantities of text rapidly [12, pp. 1119–1126]. Consequently, distance education institutions need assessment models that evaluate the learning process, oral explanation, reflection, project work, and students' ability to apply knowledge rather than relying exclusively on unsupervised written products.

A third challenge is privacy. AI language platforms may process users' texts, audio recordings, prompts, and other personal information. Hockly identifies learner-data collection and privacy as important concerns in AI-supported English language teaching [3, pp. 445–451]. UNESCO similarly emphasizes the need for data protection and human-centred governance when AI is introduced into education [11, pp. 18–27].

A fourth challenge is algorithmic bias. AI models learn patterns from large datasets, which means that the language and cultural representations available in their training data can influence generated outputs. UNESCO warns that data-poor populations and marginalized communities may be underrepresented in AI training data, potentially resulting in further marginalization of their perspectives [11, pp. 14–17]. This issue is especially relevant to foreign language education because language learning is inseparable from culture, identity, and intercultural communication.

A fifth challenge is unequal access. AI-supported distance learning requires suitable devices, internet connectivity, electricity, and digital literacy. UNESCO reports that about half a billion students were not reached by remote learning during school closures, while approximately 3.2 billion people did not use mobile internet services despite living within mobile broadband coverage [2, pp. 124–142]. Consequently, introducing advanced AI without addressing digital inequality can increase rather than reduce educational disparities.

Analysis and Discussion

The evidence suggests that AI should be understood as a pedagogical instrument rather than as an autonomous teacher. The distinction is important because language learning is not limited to the acquisition of grammatical knowledge. Effective foreign language education involves communication,

interaction, motivation, intercultural competence, critical thinking, identity formation, and social participation.

AI is particularly strong in providing repetition, immediate responses, large-scale text generation, and personalized practice. Human teachers, by contrast, remain essential for interpreting learner needs, designing pedagogical sequences, evaluating complex performance, providing emotional and social support, and developing intercultural awareness. This complementarity is consistent with UNESCO's human-centred approach to educational technology [2, pp. 66–84; 11, pp. 28–38].

The role of AI in speaking education illustrates this relationship clearly. AI conversational agents can offer learners virtually unlimited opportunities to practice target-language production. Unlike a classroom where one teacher may have to divide speaking time among many students, an AI system can interact individually with learners. Satar and Özdener's earlier study of synchronous computer-mediated communication demonstrated that technology-mediated interaction can contribute to speaking development and can influence learner anxiety [13, pp. 595–613]. Contemporary AI extends this principle by allowing interaction with a conversational system rather than requiring a fixed human partner.

Nevertheless, AI conversation should not be equated with authentic human communication. Human interaction contains emotional nuance, cultural interpretation, pragmatic ambiguity, non-verbal signals, and interpersonal relationships that AI cannot fully reproduce. Therefore, AI speaking practice should supplement rather than replace communication with teachers and other learners.

Writing instruction presents a similar pattern. AI-generated feedback can be rapid, detailed, and available at any time. Students may use it to identify recurring grammatical errors, compare alternative formulations, and revise drafts. However, excessive reliance on AI may weaken learners' independent writing abilities if the technology begins to generate substantial portions of the text instead of supporting the learner's own composition. Godwin-Jones therefore emphasizes the importance of teacher mediation when AI writing tools are incorporated into language instruction [8, pp. 5–24].

The issue of assessment requires particular attention. If students can use generative AI to produce written assignments, institutions need to reconsider what constitutes valid evidence of learning. Automated AI-detection systems should not be treated as infallible solutions because the reliability of AI-generated-text detection varies according to the system, text, language, and context. A more robust pedagogical response is to redesign assessment. Teachers can require drafts, reflections, oral defenses, process portfolios, classroom interaction, source evaluation, and personalized tasks. Such approaches evaluate not merely the final text but also the learner's reasoning and communicative competence.

Teacher competence is therefore a central factor in successful AI integration. Kohnke, Moorhouse and Zou emphasize that educators and learners need digital competencies to use ChatGPT effectively and ethically [10, pp. 537–550]. AI literacy should include the ability to formulate appropriate prompts, evaluate AI-generated information, recognize potential bias, protect personal data, acknowledge AI assistance, and understand the limitations of automated feedback.

The pedagogical model that emerges from the literature can be described as “teacher-guided AI-assisted distance learning.” In this model, the teacher determines learning objectives, selects appropriate AI applications, establishes ethical rules, monitors learner progress, validates AI-generated materials, and provides human feedback. The learner uses AI for additional practice, experimentation, self-correction, and autonomous study. AI performs repetitive or adaptive functions but does not determine educational goals independently.

This model also corresponds to broader ethical principles for AI in education. Nguyen et al. emphasize that AI integration requires consideration of issues including transparency, accountability, fairness, privacy, and human agency [14, pp. 4221–4241]. These principles are particularly important in distance learning because the physical separation between teachers and learners may make technological mediation more extensive.

The rapidly growing research base also demonstrates the need for more rigorous evidence. The 2024 systematic review of ChatGPT and language education identified 36 selected studies from an initial pool of 523 records and concluded that longitudinal research, diversified educational contexts, stakeholder perspectives, and assessment of feedback quality remain important research gaps [4]. A separate systematic review of ChatGPT for L2 learning identified 44 studies and noted that many studies focused on EFL university learners and often employed relatively small samples [5]. These findings indicate that enthusiasm about AI should be accompanied by methodological caution.

The geographical concentration of research is another concern. A systematic review of conversational AI in English language teaching found that all 32 studies included in its analysis were conducted in Asian EFL contexts, with quasi-experimental and cross-sectional designs being particularly common [15]. This suggests that evidence from Asia is substantial but that more research is needed across Africa, Latin America, Europe, Central Asia, and other educational environments.

For Uzbekistan and similar contexts, AI-supported distance foreign language education could be especially useful for expanding access to English practice beyond formal classroom hours. However, successful implementation should consider local curricula, teacher preparation, students' digital literacy, internet accessibility, language-specific needs, and cultural context. AI-generated materials should be reviewed by qualified educators before being used as authoritative instructional content.

The central pedagogical principle should therefore be controlled integration. Teachers should not ask whether AI can perform a particular task more quickly than a human. Instead, they should ask whether using AI improves the educational process and whether learners develop greater linguistic competence, autonomy, critical thinking, and communicative ability as a result.

Conclusion

Artificial intelligence is becoming an increasingly important component of distance foreign language education. The reviewed literature demonstrates that AI can expand opportunities for individualized learning, conversational practice, automated feedback, writing support, vocabulary development, learner autonomy, and teacher-assisted content creation. Empirical research provides evidence that AI-mediated speaking activities can improve language performance and willingness to communicate, while AI-generated writing feedback can provide useful assistance and accessibility.

At the same time, the available evidence does not justify the assumption that AI is inherently superior to human instruction. Research comparing GPT-4 feedback with human-tutor feedback found no statistically significant difference in learning outcomes, illustrating that the effectiveness of AI depends on how it is pedagogically integrated [9]. AI also introduces significant challenges involving inaccurate information, bias, privacy, academic integrity, overdependence, and unequal access.

The most appropriate approach is therefore not replacement but integration. Teachers should remain responsible for learning objectives, curriculum design, assessment, ethical supervision, and meaningful human interaction. AI should function as an additional resource that increases opportunities for practice and feedback while preserving learner agency.

Future research should prioritize longitudinal and experimental studies with larger and more diverse samples, different proficiency levels, different foreign languages, and varied educational contexts. Researchers should also investigate how AI influences long-term language development, critical thinking, learner autonomy, motivation, intercultural competence, and teacher workload. Greater attention should be paid to Central Asian and other underrepresented educational contexts.

Ultimately, the pedagogical value of artificial intelligence in distance foreign language education will depend not on the sophistication of the technology alone but on the quality of its educational integration. A human-centred, evidence-based, ethically responsible model offers the strongest basis for ensuring that AI contributes to language learning without undermining the central role of teachers and learners.
